

“Deep fire topology:  
Understanding the role  
of landscape spatial  
patterns in wildfire  
susceptibility ”

# Motivation: landscape topology

- We want to understand how different landscape and rural/urban interface structures impact the potential wildfire risk, in order to provide useful insights to trigger actions to mitigate future expected losses.
- Identify and extract useful topological features that can be used in related models.
- Analyze the role of connectivity, continuity, adjacency, and dispersion of the land cover when predicting future wildfire risk.

Geometrical

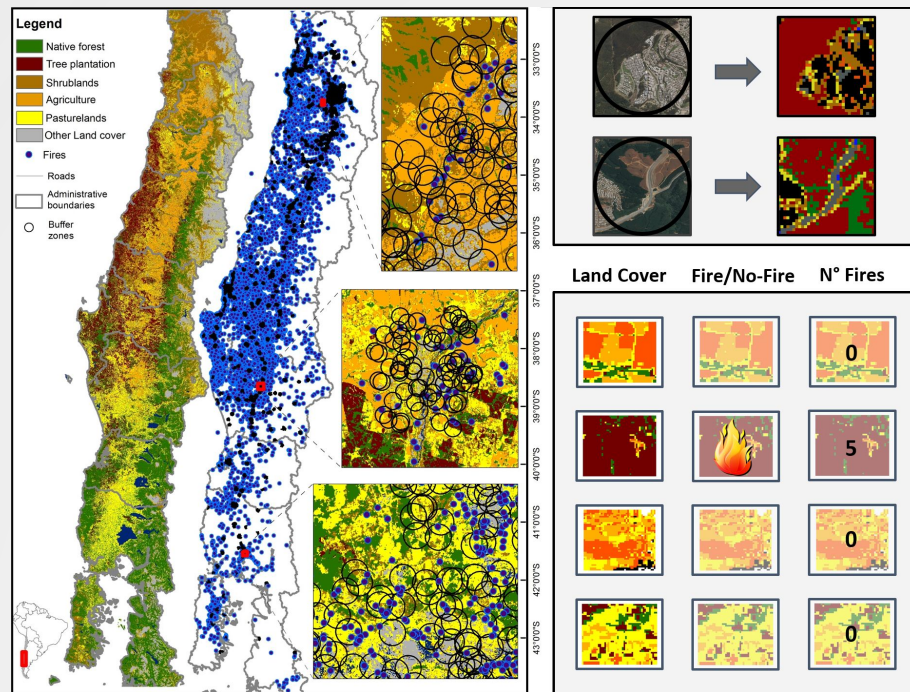

Topological

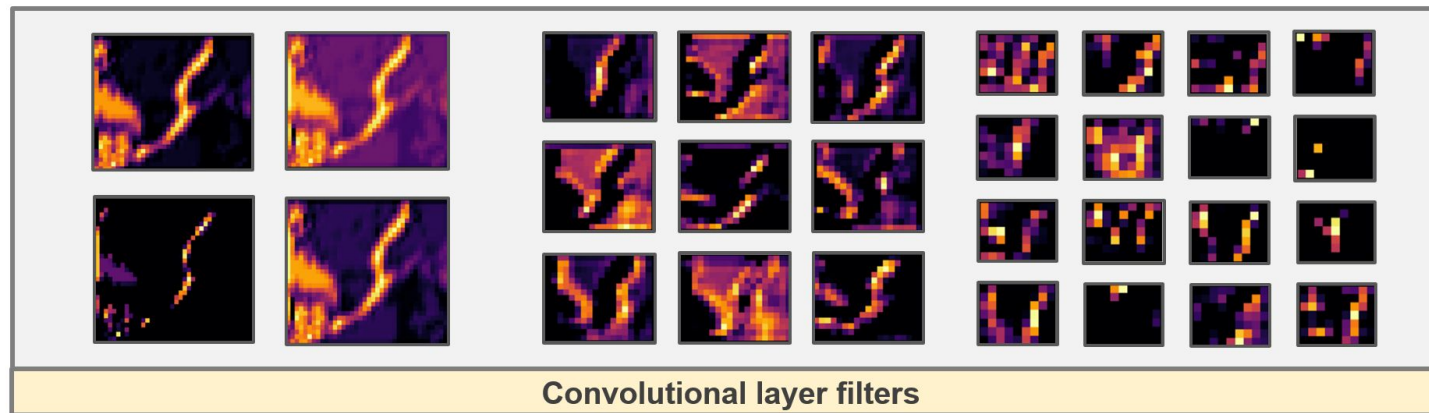

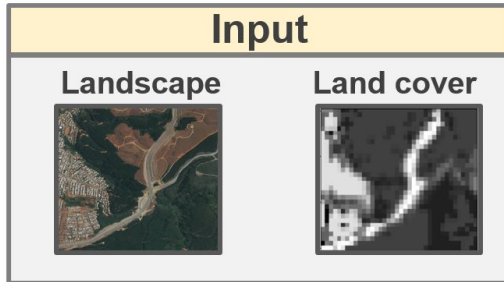

# Data mining

- **Dataset:** ~ 18,000 satellite images from Google Earth Engine. Land cover layer obtained from spectral analysis (30m resolution) is transformed into a grayscale 32x32 geotiff file.
- **Location:** south-central Chile (212,000 km<sup>2</sup>), corresponding to 28% of the country which accounts for 98.5% of the historical fire occurrence.
- **Binary label “fire”:** Classification label (1: fire positive, 0: negative) between 2013 – 2015.

99.3%

0.7%

# Risk levels

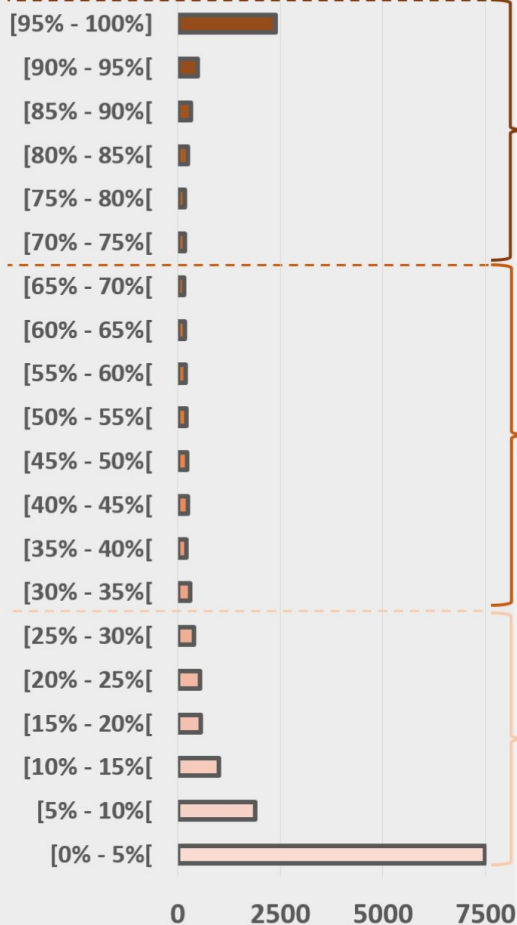

The model is able to determine dangerous/risky topologies based on the combination, adjacency, area covered, and discontinuities of different land-covers in the landscape.

E.g., Dense urban areas with certain grass/trees.

Large areas of continuous flammable land covers

## Classification risk frequency

## Landscape

Dominant LCs:  
shrublands (29.6%),  
grasslands (20.3%)

Components: 118  
Simpson index: 0.26

Dominant LCs:  
shrublands (31%),  
grasslands (22.7%)

Components: 103  
Simpson index: 0.29

Dominant LCs :  
shrublands (30%),  
croplands (26.5%)

Components: 88  
Simpson index: 0.39

## Attention maps

Dominant LCs:  
shrublands (28%),  
grasslands (19%)

Components: 45  
Simpson index: 0.40

Dominant LCs:  
shrublands (29%),  
grasslands (22%)

Components: 35  
Simpson index: 0.49

Dominant LCs :  
Croplands (29.2%),  
shrublands (25.7%)

Components: 29  
Simpson index: 0.55

## Risk analysis: full dataset summary

### High risk

Low diversity landscapes dominated by forest plantation, agriculture land, and high population density.

### Medium risk

Heterogeneous landscapes characterized by a similar proportion of the most common land covers and low population density.

### Low risk

Homogeneous landscapes dominated by native forest and low population density.

### Grad-CAM

### Guided backpropagation

### Performance metrics

### Land cover proportions

#### High risk

#### Medium risk

#### Low risk

#### All samples

# Future work

- ▶ **Global implementation results including millions of fires and extra layers (climatic, demographic, etc.) as part of the images or inputs of independent networks.**
- ▶ **Derive/evaluate meaningful and realistic actions to transform high risk landscapes into low risk ones.**
- ▶ **Deploy the open source version in GitHub and Azure services.**

# Thanks for your attention
